

COLORADO

WATER SUPPLY OUTLOOK REPORT

FEBRUARY 1, 2000

Summary

Increased snowfall during January brought some relief to Colorado's dry mountains. Snowpack percents of average increased significantly from last month in nearly all basins. While the latest readings are an improvement, the state's snowpack remains well below average, especially across the southern mountains. With only two remaining months in the average accumulation season, water users should continue to closely monitor the mountain snowpack conditions. The improved snowpack has resulted in improvements in streamflow forecasts, however, most forecasts remain below average to well below average. Reservoir storage continues to track at above average volumes and should help supplement below average flows in some locations.

Snowpack

During the last week of January, several strong storms brought heavy snow accumulations to Colorado's mountains. These storms increased the snowpack percent of average in all basins except the Arkansas, which remained unchanged during the month. The greatest increase over last month's percentages were seen in the Gunnison Basin, which increased from 32% to 61% of average, followed by the Colorado Basin, which increased from 51% to 79% of average. The highest snowpack percentages were measured across northern Colorado, and include the North and South Platte, and the Yampa and White basins. Readings in these basins range from 85% to 88% of average. Snowpack percentages decrease toward the south, and the lowest percentages were measured in the Rio Grande Basin, at only 29% of average. The San Juan and Animas sub-basins are also reporting extremely low snowpack percentages as well, at only 23% and 32% of average, respectively. The current snowpack in the Gunnison, Arkansas, Rio Grande, and San Juan, Animas, Dolores, and San Miguel basins is the lowest February 1 percentage since 1990. Similarly, Colorado's statewide snowpack is only 66% of average, and is the lowest statewide snowpack on February 1 since the 59% of average was recorded on 1990. The current snowpack remains below last year's in all basins, ranging from 33% of last year in the Rio Grande Basin, to 98% of last year in the South Platte Basin. Statewide, the current readings are only 75% of last year's.

Precipitation

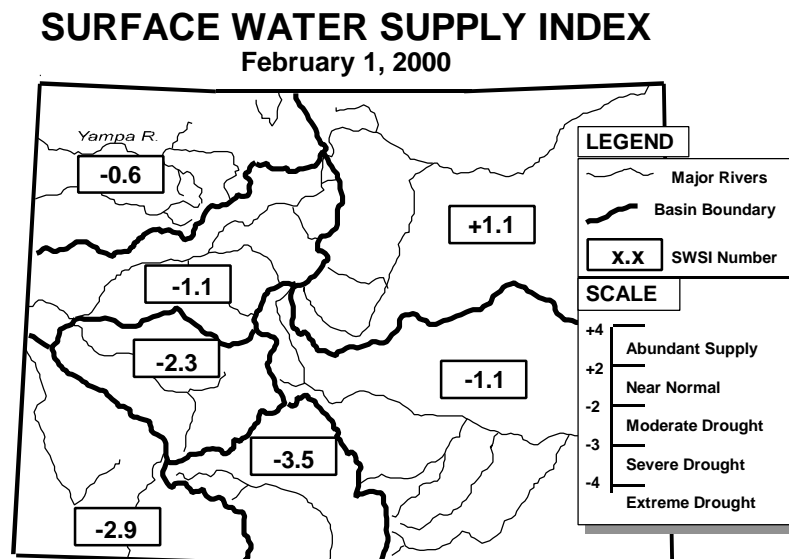

January ended the string of consecutive months with below average precipitation for most of Colorado. While southwestern Colorado received near average precipitation in January, it was the first month that was near average since September 1999 in the Rio Grande and the combined San Juan, Animas, Dolores, and San Miguel basins. Elsewhere across the state, precipitation was generally above to well above average. Those basins reporting some of the highest monthly totals include the Arkansas, Gunnison, Colorado and Yampa and White basins. This wet month helped improve water year percentages statewide. While seeing improvements, water year percentages remain below average statewide and remain extremely low across southwestern Colorado. As a whole, the state recorded 136% of average precipitation for the month of January, but remains at only 53% of average for the first four months of the 2000 water year.

Reservoir Storage

Reservoir storage remains above average in all of the major river basins. The highest storage volumes, as a percent of average, are in the Arkansas Basin, where storage is 261% of average. The Rio Grande Basin is also reporting well above average storage at 160% of average. Statewide storage remains well above average as well at 140% of average. This volume exceeds the average by slightly more than 1.2 million acre-feet of water. While all basins are reporting above average storage, all basins are also reporting volumes near or above last year's storage on this date. Again, the Arkansas Basin is reporting the greatest increase over last year, at 121% of last year. Statewide storage is 11% above last year's. Much of this additional water was stored during last summer's wet monsoon season and will be increasingly valuable as we enter a potentially very dry summer in 2000.

Streamflow

While the additional snowpack has helped ease concerns about summer water supplies, they have certainly not eliminated it. Nearly the entire state can continue to expect below average streamflow volumes. Conditions worsen across the southwestern portion of the state where well below average runoff is forecast. Of greatest concern, are those streams in the Animas, San Juan, and Rio Grande basins, where forecasted spring and summer runoff ranges from only 30% to 50% of average. Along some of the smaller streams and tributaries in these basins, forecasted runoff is the lowest since the drought years of 1977 and 1981. At this time in the winter accumulation season, water users in these basins should make preparations for a dry runoff season, with low peak flows that rapidly recede after the meager snowpack melts.

The Surface Water Supply Index (SWSI) is a weighted value derived for each major basin which generally expresses the potential availability of the forthcoming season's water supply. The components used in computing the index are reservoir storage, snowpack water equivalent, and precipitation. The SWSI number for each basin ranges from a -4.0 (prospective water supplies extremely poor) to a +4.0 (prospective water supplies plentiful). The SWSI number is only a general indicator of surface water supply condition. Further data analysis may be required in specific situations to more fully understand the impacts of abnormally dry or wet conditions suggested by the SWSI. Development of the SWSI has been a cooperative effort between the Colorado State Engineer's Office and the Natural Resources Conservation Service.

GUNNISON RIVER BASIN as of February 1, 2000

*Based on selected stations

Snowfall during January has done a lot to improve the snowpack conditions in the Gunnison Basin. There is over double the amount of snow in the basin on February 1 as there was a month ago. Despite the additional snow that boosted the snowpack, 29% of average from last month, the accumulation amounts are still significantly below average at only 61%. There is only 72% of the amount of snow there was last year at this time. Precipitation in the lower elevations was 159% of average during January, and the water year total is now 72% of average. The reservoir storage is 22% above average for this time of year, which is about the same storage as last year at this time. Streamflow forecasts for the upcoming runoff season are slightly lower than last month and continue to be much below average for most of the forecast points in the basin. Forecasted flow volumes range from only 43% of average at the inflow to Paonia Reservoir, to 76% of average on the Taylor River below Taylor Park Reservoir.

* 90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual volume will exceed the volumes in the table.

The average is computed for the 1961-1990 base period.

- (1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.
(2) - The value is natural volume - actual volume may be affected by upstream water management.

UPPER COLORADO RIVER BASIN as of February 1, 2000

*Based on selected stations

The Colorado Basin received some much needed additional snowfall during January, boosting the accumulation amounts to over twice the amount there was last month. The snowpack is now at 79% of average on February 1, which is 28% of average higher than on January 1. Snowpack is highly variable throughout the basin with percentages ranging from only 53% of average in the Plateau Creek Watershed, to 103% of average in the Muddy Creek Watershed. Precipitation in the basin was 159% of average during January, and the total precipitation for the water year is now at 74% of average. The combined reservoir storage volume in the basin is 28% above average for this time, which is about the same as last year's February 1 storage. All of the streamflow forecasts for the upcoming runoff season have increased from last month. Forecasts range from 75% of average on the Roaring Fork at Glenwood Springs, to 94% of average at the inflow to Lake Granby.

SOUTH PLATTE RIVER BASIN as of February 1, 2000

*Based on selected stations

The South Platte Basin had nearly continuous snowfall in the higher elevations during the second half of February. The additional snowfall has nearly doubled the amount of snow accumulation and has boosted the percent of average from 64% of average on January 1, to 85% of average on February 1. The snowpack remains relatively uniform throughout the basin with percentages ranging from 80% of average in the Big Thompson Watershed, to 91% of average in the St. Vrain Watershed. Precipitation in the basin was 115% of average during the month of January, and the water year total is now 71% of average. Reservoir storage remains above average for this time of year at 113%, which is 17% more than last year at this time. Streamflow forecasts for the upcoming runoff season have improved since last month's forecasts, but they all remain below average. Forecasts range from only 64% of average flow at the Inflow to Antero Reservoir, to 94% of average on the Big Thomson River at mouth near Drake.

YAMPA, WHITE, NORTH PLATTE AND LARAMIE RIVER BASINS as of February 1, 2000

*Based on selected stations

These basins received significantly above average amounts of snow for the month of January, which has increased the snowpack percent of average from only 64% of average on January 1, to 84% of average on February 1. The Yampa and White basins have the highest snowpack percent of average in the state at 88%, which is nearly the same amount as last year at this time. The snowpack in the North Platte Basin is at 86% of average, which is 14% less than last year at this time. Precipitation in these basins during January was 144% of average, but the water year total is only 79% of average. The combined reservoir storage in these basins is at 115% of average, which is about the same as last year at this time. The upcoming runoff season is still forecasted to be below average at all of the forecast points in these basins. The forecasts are highly variable depending on location and range from only 64% of average on the Laramie River near Woods, to 86% of average on the Yampa River at Steamboat Springs.

* 90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual volume will exceed the volumes in the table.

The average is computed for the 1961-1990 base period.

- (1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.
(2) - The value is natural volume - actual volume may be affected by upstream water management.

ARKANSAS RIVER BASIN as of February 1, 2000

*Based on selected stations

There was just enough additional snowfall in the Arkansas Basin during January to hold the snowpack percent of average at 62%, which is the same as last month. The Purgatory Watershed remains the high spot in the basin with snowpack amounts measuring 85% of average, while the Cucharas and Huerfano basins have only 54% of average snowpack amounts. There is only 72% of the amount of snow in the basin that there was last year at this time. Precipitation was 155% of average through January, and the water year total is now 86% of average. The combined reservoir storage in the basin is at 261% of average at this time, which is 21% more storage than last year at this time. Some of the reservoirs are as high as 400% of their normal storage level due largely to extremely high flows last spring. All of the streamflow forecasts for the upcoming runoff season remain below average at this time. They range from only 55% of average flow on Grape Creek near Westcliffe, to 80% of average on the Huerfano River near Redwing.

UPPER RIO GRANDE RIVER BASIN as of February 1, 2000

*Based on selected stations

Even though the Rio Grande Basin managed to receive slightly above average snowfall in the higher elevations during January, its snowpack conditions remain extremely low so far this season. On February 1 the basin has the lowest measured snowpack percent of average in the state at only 29% of average. On average, January is a time when the Rio Grande Basin receives very little snow while February and March are some of the biggest snowfall months, which leaves some hope that the future may provide the much needed snow accumulation. Precipitation in the basin was only 76% of average for January and the water year total is only 29% of average. Fortunately, the combined reservoir storage in the basin is 60% above average, which is 16% more than last year at this time. Most of the streamflow forecasts have gone down from last month. Most are much below average and many are below 50% of average. Forecasts range from only 19% of average flow on the San Antonio River at Ortiz, to 77% of average at the Trinchera Water Supply.

SAN MIGUEL, DOLORES, ANIMAS, AND SAN JUAN RIVER BASINS as of February 1, 2000

*Based on selected stations

These basins managed to pick up nearly average amounts of snowfall during January, which has boosted their combined snowpack accumulation from only 17% of average on January 1, to 41% of average on February 1. The snowpack percentages are highly variable throughout the basins ranging from only 23% of average in the San Juan Watershed, to 68% of average in the San Miguel Watershed. There is only 47% of the amount of snow in the basin's there was last year at this time. There was 114% of average precipitation during January, but the water year total is now only 34% of average. The combined reservoir storage level in these basins is 116% of average for this time of year, but without an improved snowpack this could easily turn to below average storage during the upcoming runoff season. There is 17 % more storage than last year at this time. All of the forecasted streamflows for this runoff season remain below average and most are lower than last month. Forecasts range from only 31% of average on the Navajo River at OSO Diversion, to 66% of average at the San Miguel River near Placerville.
